5 METHOD TO CONTROL THE UPDATE FREQUENCY OF A POSITIONING  
DEVICE BY A MOBILE TERMINAL

10 BACKGROUND OF THE INVENTION

The present invention generally relates to position estimating devices and, more particularly, to a method of controlling the update frequency of a position estimating device in a mobile terminal.

15 The wireless communication industry has made phenomenal strides in commercial operations in the United States and the rest of the world. Growth in major metropolitan areas has far exceeded expectations. If this trend continues, it is possible that wireless communications will provide the bulk of telecommunication services in some areas. As a result of this growth, wireless communication services have become more affordable. In light of the recent trend of competitive air-time rates, customers may  
20 choose to make wireless communication devices their primary means of personal communication. The popularity of wireless communication devices is further enhanced by their ability to be used for non-voice communication, such as facsimile and data transmission.

In the near future, wireless communication devices will incorporate position  
25 estimating devices to enhance the function and utility of the wireless communication device. Perhaps the best known use of position estimating technology is for navigation. Another common use for position estimating devices is to identify facilities, such as hotels or restaurants, that are nearby the current position of the wireless communication device. Position information can also be used to enhance intrinsic functions of wireless

5 communication devices. For example, position information can be used to improve cell  
reselection or hand-off decisions in mobile terminals. Examples of how position  
information may be used to enhance intrinsic functions of the mobile terminal are  
illustrated in the following U.S. patent applications: Serial No. 09/498,785 entitled  
“Position Assisted Handoff in a Wireless Communication Network”; Serial No.  
10 09/505,431 entitled “Position Assisted Service Selection”; and Serial No. 09/498,772  
entitled “System and Method For Improving Channel Monitoring In a Cellular System.”

Position estimating devices have a broad variety of uses and can significantly  
enhance the utility and, therefore, the desirability of wireless communication devices

## 15 BRIEF SUMMARY OF THE INVENTION

The present invention is a mobile terminal having a GPS receiver or other position  
estimating device and control logic. The control logic periodically executes a routine to  
update the current location of the mobile terminal. The position update frequency, i.e., the  
20 frequency at which position updates are performed, is varied depending upon the distance  
between the mobile terminal and a point of interest to reduce the power consumed by the  
position estimating device. A reference position for the point of interest is stored in the  
mobile terminal for comparison with the current position of the mobile terminal. In one  
embodiment, the position update frequency is adjusted so that position updates are less  
25 frequent when the mobile terminal is far away from the point of interest and more  
frequent when the mobile terminal is close to the point of interest. The frequency of  
position updates may also be dependent on the velocity of the mobile terminal. That is,

5 the update frequency is made less frequent when the mobile terminal is stationary or moving slowly.

## BRIEF DESCRIPTION OF THE DRAWINGS

10 Figure 1 is a block diagram illustrating the functional elements of an exemplary mobile terminal;

Figure 2 is a flow chart illustrating an exemplary position update procedure according to the present invention;

Figure 3 is a schematic representation of a public and private radiocommunication system;

15

Figure 4 is an exemplary graph illustrating the relationship between the position update frequency and channel search frequency of the mobile terminal, and the distance between the mobile terminal and a private radiocommunication system.

5

## DETAILED DESCRIPTION OF THE INVENTION

Referring now to the drawings, Figure 1 is a block diagram of a mobile terminal indicated generally by the numeral 20. The term "mobile terminal" as used herein may comprise a cellular radiotelephone; a Personal Communications Service (PCS) terminal that may combine a cellular radiotelephone with data processing, facsimile and data communications capabilities; a Personal Digital Assistant (PDA) that may include a radiotelephone, pager, Internet/intranet access, Web browser, organizer, and/or calendar; a conventional laptop computer, a palmtop computer, or other appliance that includes a radiotelephone transceiver. Mobile terminals may also be referred to as "pervasive computing" devices.

Mobile terminal 20 may employ a wide variety of communication standards and protocols, which are published by organizations such as the Telecommunications Industry Association/Electronics Industry Association (TIA/EIA) and the European Telecommunication Standards Institute (ETSI), including without limitation Time Division Multiple Access (TDMA) standards such as TIA/EIA-136 and the Global System for Mobile Communications (GSM), Code Division Multiple Access (CDMA) standards such as TIA/EIA-95, Wideband Code Division Multiple Access (WCDMA) standards such as cdma2000, Universal Wireless Communications (UWC) 136, and satellite communication standards such as Globestar. The details of the communication protocols used by the mobile terminal 20 are not material to the invention.

5 Mobile terminal 20 comprises a main control unit 22 for controlling the operation of the mobile terminal 20 and memory 24 for storing control programs and data used by the mobile terminal 20 during operation. Input/output circuits 26 interface the control unit 22 with a keypad 28, display 30, audio processing circuits 32, receiver 38, transmitter 40, and positioning receiver 50. The keypad 28 allows the operator to dial  
10 numbers, enter commands, and select options. The display 30 allows the operator to see dialed digits, stored information, and call status information. The audio processing circuits 32 provide basic analog audio outputs to a speaker 34 and accept analog audio inputs from a microphone 36. The receiver 38 and transmitter 40 receive and transmit signals using shared antenna 44.

15 Local terminal 20 may also include an alternative interface 56, such as a “Bluetooth” air interface, which may use a separate antenna 58. Bluetooth is a universal radio interface in the 2.45 GHz frequency band that enables portable electronic devices to connect and communicate wirelessly via shortrange, adhoc networks. Persons interested in various details regarding the Bluetooth technology are referred to the article entitled  
20 “Bluetooth-the universal radio interface for ad hoc, wireless connectivity” authored by Jaap Haartsen, which can be found in the Ericsson review, Telecommunications Technology Journal, No. 3, 1998, the disclosure of which is incorporated herein by reference. For the purposes of the present invention, only Bluetooth features of immediate interest are described herein.

25 In Bluetooth systems, a fixed station may act as a master device and continuously transmit INQUIRE messages for receipt by any mobile terminals 20 that

5 may be in the vicinity of the fixed station. A mobile terminal 20 in the vicinity of the  
fixed station would recognize the presence of the fixed station. The mobile terminal 20  
could then initiate communications with the fixed station over the Bluetooth interface.  
The fixed station may be part of an alternate communication network as will be  
hereinafter described in greater detail. Additionally, the mobile terminal 20 includes a  
10 position estimator 50 electrically and operatively coupled to a navigation signal antenna  
52. Position estimator 50 functions to determine the geographical position or location of  
the mobile terminal 20 at selected times. Position estimator 50 generates geographic  
position estimates under the control of the control unit 22 using navigation signals  
received through navigation signal antenna 52. These navigation signals may be  
15 broadcast by navigation satellites, e.g. those of the Global Positioning System (GPS).  
GPS signal reception and position determination therefrom are well known in the art.  
Such position determination is disclosed in U.S. Patent 4,968,981 to Sekine, et al.,  
entitled "GPS Receiver Apparatus," the disclosure of which is incorporated herein in its  
entirety. Other position determining technologies are also available, for example the  
20 Russian equivalent to the US operated GPS system. There are also terrestrial based  
position and navigation systems (e.g. LORAN), which could be used in the practice of the  
present invention.

Navigation signal antenna 52 receives navigation signals, e.g., from navigation  
satellites, for the calculation of position estimates. The size and location of navigation  
25 signal antenna 52 is illustrative only, and may in practice be pivotably or retractably  
mounted, may be detachable, or may be designed into the housing of mobile terminal 20.

5 With a position estimator 50, mobile terminal 20 gains expanded functionality and flexibility in its operations. In particular, the mobile terminal 20 can use position estimates for a wide variety of purposes, such as to improve channel reselection and hand-off decisions, or to access a database of location specific information depending on the current location of the mobile terminal. For example, pending U.S. Patent application  
10 number 09/498,785 entitled "Position Assisted Handoff Within A Wireless Communication Network" discloses a method for making hand-off decisions based on the current location of the mobile terminal 20. U.S. Patent application number 09/505,301 entitled "Position Assisted Service Selection" discloses a method for choosing a service provider based on the current position of the mobile terminal 20. U.S. Patent application  
15 number 09/546,720 entitled "Mobile Terminal With Local Area Database" discloses a mobile terminal 20 that uses the current position of the mobile terminal 20 to retrieve location specific information, such as the nearest hotel, from a database in the mobile terminal 20. U.S. Patent Application No. 09/498,772 entitled "System and Method For Improving Channel Monitoring In a Cellular System" discloses a method for monitoring  
20 channels on a neighbor list. U.S. Patent Application No. \_\_\_\_\_ entitled "System Proximity Detection Method By Mobile Stations" discloses a method for acquiring service with a private radio communication system based on proximity to the private system. These applications are incorporated herein by reference.

The present invention is not concerned specifically with how position information  
25 is used by the mobile terminal 20 and the above cited examples therefore should not be construed as limiting the invention in any way. It is simply assumed for purposes of

5 describing the present invention that position information is used in some manner by the mobile terminal 20 for some useful but unspecified purpose. The present invention relates specifically to the manner in which the current position of the mobile terminal 20 is updated. In particular, the present invention relates to a method for controlling the position update frequency of the position estimator 50 based on the distance of the mobile  
10 terminal 20 relative to a specific point of interest.

Figure 2 is a flow diagram illustrating an exemplary method for determining the position update frequency of the mobile terminal 20. At block 60, a triggering event causes the control unit 22 to initiate the position update routine. The triggering event may, for example, be the expiration of a timer used by control unit 22 that determines the  
15 position update frequency of the mobile terminal 20. This timer (not shown) may be initially set to a predetermined default value and updated as hereinafter described. Upon expiration of the timer or upon the occurrence of some other triggering event, the mobile terminal 20 determines its current position (block 62) and thereafter computes the distance D of the current position to a reference position corresponding to a point of  
20 interest (block 64). Additionally, the mobile terminal 20 may compute the speed or velocity of the mobile terminal 20 based on two or more position estimates over a period of time. In block 66, the mobile terminal 20 adjusts the position update frequency as needed based on the computed distance D, velocity V, or a combination of the distance D and velocity V. At block 68, the mobile terminal can optionally perform additional acts  
25 or steps. For example, current position of the mobile terminal 20 may optionally be returned to a calling procedure or application that has requested the current position of the

5 mobile terminal 20. Additionally, the mobile terminal 20 may take action based on the distance D between the current position of the mobile terminal and the reference position. In this case, the mobile terminal 20 may compare the distance D to a threshold distance at block 70. If the distance D is less than the distance threshold, the mobile terminal 20 may perform a predetermined action (step 72). For example, the predetermined action may

10 comprise acquiring service with an alternate network when the distance D is within a predetermined radius of a reference position of the alternate network, as will be described in greater detail below. After the additional steps represented by block 68 are performed, the position update procedure terminates (block 74).

The algorithm for adjusting the position update frequency of the mobile terminal

15 20 at block 66 may be as simple or as complex as needed or desired in a particular application. In one embodiment of the invention, the position update procedure employs a sliding scale so that position updating becomes more frequent as the mobile terminal 20 moves closer to the point of interest and becomes less frequent as the mobile terminal 20 moves farther from the point of interest. A sliding scale can be implemented, for

20 example, by comparing the computed distance D of the mobile terminal 20 from the point of interest to one or more predetermined set points and adjusting the update frequency accordingly. By reducing update frequency as the mobile terminal 20 moves away from the point of interest, the power drain on the battery can be significantly reduced.

Figure 3 illustrates one possible application where the control of the position

25 update frequency of a positioning device can be useful. Figure 3 shows a mobile terminal 20 in a vehicle traveling within the coverage area of a public land mobile network 100.

5 Public land mobile network (PLMN) 100 comprises a base station 110 coupled to an antenna 112. Base station 110 provides radiocommunication services to various mobile terminals 20 within its area of coverage, or cell. Base station 110 is connected to a mobile switching circuit (not shown), which in turn is connected to the public switched telephone network (not shown).

10 Proximate to PLMN 100, and possibly within or partially within the coverage area of PLMN 100, is a private wireless telephone system (PWTS) 200. PWTS 200 is one example of an alternate network.. PWTS 200 provides radiocommunication services within a facility 205. In the exemplary embodiment described herein, the PWTS 200 is structurally and functionally similar to PLMN 100. PWTS 200 comprises a plurality of  
15 base stations 210 located strategically throughout facility 205 to provide continuous coverage to mobile terminals 20 therein. Base stations 210 may be interconnected with a MSC (not shown) in the PLMN 100 or may be interconnected to the public switched telephone network (not shown). Interconnection with the PLMN 100 enables the same mobile terminal 20 to be used in both the PLMN 100 and PWTS 200. Thus, the user is  
20 able to roam seamlessly through the PLMN 100 and PWTS 200. Transfer between the PLMN 100 and PWTS 200 in this case are transparent to the user.

Base stations 210 within PWTS 200 are functionally similar to base stations 110 within PLMN 100, but also differ in several respects. Base stations 210 are typically of lower power than those used in the PLMN 100 to avoid interference with the PLMN 100  
25 and, consequently, are deployed closer together to provide coverage over the entire facility 205. An example of a base station 210 designed for use in a PWTS 200 is the

5 PicoBase™ system produced by Ericsson, Inc. Base station 210 may use the same interface as the PLMN 100, or may employ an alternate interface. One alternate interface is a Bluetooth interface that operates in the 2.45 GHz frequency band.

Facility 205 may comprise any geographic locus, such as a shopping mall, sports arena, office building or park, hotel, apartment complex, airport, university campus, etc.

10 Tenants of facility 205 may wish to provide a private radiocommunication system for use by mobile terminal users therein for a broad variety of reasons, including cost control and increased availability of personnel as users migrate from dependence on desktop telephones to mobile terminals. PWTS 200 is typically operated by a business, such as the tenant of facility 205 or the service may be provided by a third party and leased to  
15 such business on a flat rate. In either case, users typically do not incur air-time charges for use of radiocommunication services in PWTS 200. Thus, users approaching and entering facility 205 will generally desire to acquire service with the PWTS 200 whenever possible, to avoid air-time charges incurred when using the PLMN 100.

When a mobile terminal 20 powers on, it will attempt to locate a control channel  
20 in either the PLMN 100 or the PWTS 200, from which it can, for example, obtain overhead information regarding system operations, receive paging messages and initiate calls. Various techniques are available for locating control channels in public land mobile networks, which techniques are typically specified by the applicable radiocommunication standards. For example, techniques for finding a control channel once the mobile terminal  
25 20 is ordered to search for a control channel, such as by first ranking all the channels in signal strength, are described in TIA/EIA standard ANSI-136 and ETSI's GSM standard,

5 which are incorporated herein by reference. An additional example of techniques by  
which control channels can be located is found in U.S. Patent No. 5,570,467 to Sawyer,  
entitled "Method and Apparatus for Locating a Digital Control Channel in a  
Radiocommunication System", and U.S. Patent No. 6, 058, 108 entitled "Method and  
apparatus for locating a digital control channel in a radiocommunication system," the  
10 disclosures of which are incorporated herein in its entirety.

The location of known private systems to which the user has access can be stored  
in the mobile terminal 20. For example, a central point in the PWTS 200 or other private  
system may be stored in the mobile terminal 20 as the reference position and the distance  
threshold may be a radius R which defines an area encompassing the facility 205. When  
15 the position estimator 50 indicates that the mobile terminal 20 is close to a known private  
system (i.e., the distance from the current position of the mobile terminal 20 and the  
stored location is less than a predetermined threshold distance), the mobile terminal 20  
may trigger a search for a control channel associated with the PWTS 200 and acquires  
service with the PWTS 200 if a control channel is found. The control channel may be a  
20 physical channel or a logical channel. If the search is successful, i.e., a control channel is  
found, the mobile terminal 20 can acquire service with the PWTS 200. If the mobile  
terminal 20 fails to locate a suitable control channel, it may be programmed to  
periodically search for a control channel as long as its estimated current position is within  
the threshold distance from the reference position, on the assumption that the mobile  
25 terminal 20 is merely temporarily shielded from the private system's base station 210.  
Alternatively, the mobile terminal 20 could be programmed to search for a control

5 channel a predetermined number of times, and then stop searching, on the assumption  
that the PWTS 200 is inoperative, and further searches would merely waste battery  
power. In either event, this geographic position approach to initiating the search for the  
control channel of the PWTS 200 allows a total decoupling of the public and private  
systems, while simultaneously minimizing the time when the mobile terminal 20 is blind  
10 to incoming pages and the current drain associated with geographically indiscriminate  
periodic control channel searches.

The operation of position estimator 50 increases the current drain on the battery of  
the mobile terminal 20. Hence, it may not be desired to operate the position estimator 50  
on a continuous basis. Other position related applications (e.g., emergency calling) may  
15 only activate the position estimator 50 upon request, by a user command or indirectly by  
the user when enabling an application that utilizes the position of the mobile terminal 20.  
Thus, if other uses of the position estimator 50 only require infrequent position updates,  
the current drain of the position estimator 50 to support the locating of private systems,  
while providing timely discovery of the private systems, may jeopardize the objective of  
20 low impact on the current drain of mobile terminal 20.

According to the present invention, the position update frequency may be set by  
default to a relatively low value and increased as the distance to a point of interest, e.g.,  
the PWTS 200, decreases. Thus, when the position estimator 50 indicates that the mobile  
terminal 20 is close to a previously learned PWTS 200, the mobile terminal 20 may  
25 request the position estimator 50 to update its position with an increased position update  
frequency in order to avoid any delay in acquiring service with the PWTS 200, while

5 minimizing the current drain of the position estimator 50 when the mobile terminal 20 is far from any private systems. Thus, the frequency of position update becomes a function of the distance to the PWTS 200.

This function is depicted graphically in Figure 4, wherein the abscissa represents increasing distance between the mobile terminal 20 and the reference position (in km), and wherein the ordinate represents increasing frequency of position updates by the mobile terminal 20 (in  $\text{min}^{-1}$ ). The function, as represented by the first solid curve, is generally decreasing, i.e., of negative instantaneous slope, but may be of any formulation, such as linear, quadratic, inverse exponential, etc., as most effective, and as may be discovered by one of ordinary skill in the art without undue experimentation. The curve reaches a maximum as the user approaches the boundary of the private system, for example at the radius  $r$  of a system wherein the stored reference position represents the center of a circular area of coverage. As the user approaches  $r$ , mobile terminal 20 updates its position estimate more and more frequently, providing increasingly current estimates of the user's distance from the reference position. This minimizes the delay in triggering a control channel search as the user reaches  $r$  (the threshold distance, generally denoting the boundary of the private system).

The dotted curves of Figure 4 represents two possible responses of the update frequency function as the user enters the range of the private radiocommunication system and searches for a control channel. At this point, the mobile terminal 20 may cease updating its position to conserve battery power – assuming that no other function of the mobile terminal 20 is position-dependant. This response is depicted by dotted graph a.

5 Alternatively, the mobile terminal 20 may default to some intermediate frequency of  
position update  $f_d$ , as depicted by dotted graph b. This would allow the mobile terminal  
20 to take advantage of position-dependant resources within the area covered by the  
PWTS 200. These two responses are illustrative only, and a wide variety of other  
position estimate update schemes are possible, as desired or required by particular  
10 applications.

The second solid curve of Figure 4 represents the control channel search  
frequency as a function of the distance between the mobile terminal 20 and the reference  
position. The curve exhibits a step function at the boundary of the PWTS 200. Far from  
the reference position, no search for a control channel is performed, to preserve battery  
15 power. As the mobile terminal 20 moves closer to the boundary of the PWTS 200, the  
frequency of position updates increases as described above, but still no search for a  
control channel is initiated, since the mobile terminal 20 is greater than the threshold  
distance from the reference position, and is thus presumed to be outside of the coverage  
area of the PWTS 200. When the mobile terminal 20 reaches the boundary of the  
20 coverage area at  $r$ , a search for a control channel is initiated, as indicated by the step  
function depicted in the graph. This search is continued, either continuously or  
periodically, until a control channel for the PWTS 200 is found or until a predetermined  
number of access attempts have been made. If the search is successful, the mobile  
terminal 20 switches communications to the PWTS 200 and ceases its search for a control  
25 channel.

5 As a further refinement of this approach, the frequency of position updates may be dependant on the rate of change of distance of mobile terminal 20 from the point of interest. Consider the example of a user within a PWTS 200 having lunch in a place just outside the coverage of the PWTS 200, but very geographically close to the PWTS 200. In this case, as described above, the mobile terminal 20 would update its position frequently since its current position is close to the known reference position of the PWTS 200. This frequent position estimate update would be to minimize the time necessary to acquire service with the PWTS 200 when the user moves within the coverage area of the PWTS 200. In this example, however, the user does not gain any advantage from the frequent position estimate updates, since the user is not moving towards the PWTS 200. In fact, the frequent position estimate updates are counterproductive, as they cause the position estimator 50 to needlessly consume battery power. By reducing the frequency of position estimate updates when the rate of change of calculated distance from the PWTS 200 is low (even when the absolute distance to the PWTS 200 is small), battery power is conserved without a loss of timeliness of detection of the PWTS 200. Following lunch, the user moves back towards the PWTS 200 boundary. The higher rate of change of his distance from the PWTS 200 triggers more frequent position estimate updates. Thus the mobile terminal 20 will trigger its search for the PWTS 200's control channel very soon after reaching the threshold distance. If the user is relatively far from the coverage area of the PWTS 200, the mobile terminal 20 would update its position less frequently due to the increased distance, and the rate of change of that distance would have no impact.

5 Typically, the user will prefer to use a PWTS 200 over a public one, to minimize usage charges, i.e., air-time charges. Thus the mobile terminal 20 may be designed to maintain service with the PWTS 200 as long as the communication quality is sufficient. Hence, the service selection algorithm in the mobile terminal 20 may not use position estimates from the position estimator 50 to determine when to switch to the less preferred  
10 system, for example, a PLMN 100. In this case, the marginal communication quality of the downlink control channel when in idle mode may be used as a trigger event for searching for the PLMN 100. However, in order to avoid "channel dragging," in which the mobile terminal 20 is using, or will be using if a call is placed or received, a channel assigned to the PWTS 200 while far into the PLMN 100 and thereby potentially creating  
15 interference, a combination of channel quality and estimated position may be used to determine when to switch to the less preferred system. Alternatively, the threshold distance and rate of change in distance between the mobile terminal 20 and the reference position may be utilized to switch from a private to a PLMN 100 as disclosed herein to switch from a PLMN 100 to a PWTS 200.

20 The learning of the location of a PWTS 200 by the mobile terminal 20 can take various forms. Once the mobile terminal 20 is camped on the PWTS 200, the PWTS 200 can download a geographic description of its coverage area. Alternatively, the user may download the information provided on, e.g., a corporate WEB site, over a wireless link. In this case, the wireless communication system is used to download the information but  
25 is not aware of the content nor initiates the transaction. However loaded, the mobile terminal 20 may discard the information about private systems if they are not visited for

5 an extended period of time and there is a memory shortage. The user may be prompted about this proposed action.

The format of the location information may take various forms. In its simplest representation, the location is a single position. A more useful representation would be a single position and a radius, defining a circular area. An odd-shaped system may be  
10 described by multiple positions defining a boundary, forming a polygon when connected by straight lines. A wide variety of other modes of identifying boundaries of a coverage area may be utilized, as known in the art, and as may be determined by one of ordinary skill without undue experimentation.

The above formats may advantageously be augmented by a height factor, e.g.,  
15 over sea level or similar reference point. This may add precision, e.g., for a business located in a multi-story building. Thus, the distance from the mobile terminal 20 to the reference location may be computed in three-dimensional space. In all the above formats, it is envisioned that the location information concerning the PWTS 200 will be contained within the operative boundaries of the PWTS 200. As used herein, the term “within the  
20 boundaries of” includes within the system or along the boundaries of the system.

The present invention has been explicated herein in reference to an environment comprising a public and a private radiocommunication system, with the PWTS 200 being generally preferred by the user. The invention is not thus limited, however, and may be advantageously employed to switch from any first wireless system to any second wireless  
25 system about which geographic extent is known. Thus, as used herein, the term “PWTS 200” refers to its desirability vis a vis the public cellular system, and not to details of

## CLAIMS

What is claimed is:

1. A method for controlling the update frequency of a positioning device in a mobile  
10 terminal, said method comprising:  
  
storing at least one reference position in said mobile terminal; determining the  
  
current position of said mobile terminal:  
  
computing a distance of said current position of said mobile terminal from said  
  
reference position; and  
  
15 determining a position update frequency based on said distance between said  
  
current position of said mobile terminal and said reference position.
2. The method of claim 1 wherein determining a position update frequency based on  
said distance between said current position of said mobile terminal and said reference  
20 position comprises increasing said update frequency as said distance between said current  
position of said mobile terminal and said reference position decreases.
3. The method of claim 1 wherein determining a position update frequency based on  
said distance between said current position of said mobile terminal and said reference  
25 position comprises decreasing said update frequency as said distance between said current  
position of said mobile terminal and said reference position increases.

5 4. The method of claim 1 further comprising determining the velocity of said mobile terminal based on two or more position estimates.

5. The method of claim 4 wherein determining said position update frequency as a function of said distance between said current position of said mobile terminal and said  
10 reference position further comprises determining said position update frequency as a function of said distance between said current position and said reference position and said velocity of said mobile terminal.

6. The method of claim 5 wherein determining said position update frequency as a  
15 function of said distance between said current position of said mobile terminal and said reference position and said velocity of said mobile terminal comprises increasing said position update frequency as said velocity increases and decreasing said position update frequency as said velocity decreases.

20 7. The method of claim 1 further comprising:  
comparing said distance between said current position of said mobile terminal and said reference position to a predetermined threshold; and  
performing a predetermined action if said distance between said current position of said mobile terminal and said reference position meets said threshold.

25

5 8. The method of claim 7 wherein performing a predetermined action if said distance  
between said current position of said mobile terminal and said reference position meets  
said threshold comprises searching for a channel in an alternate network.

9. The method of claim 8 wherein searching for a channel in an alternate network  
10 comprises searching for a control channel in a private wireless telephone system.

10. A mobile terminal comprising:  
a transceiver transmitting and receiving signals over a wireless channel;  
memory storing at least one reference position;  
15 a position estimator to periodically determine a current position of said mobile  
terminal at a variable position update frequency; and  
control logic including a processor to calculate the distance of said mobile  
terminal from said reference position based on said current position of said  
mobile terminal and to adjust said variable position update frequency as a  
20 function of said distance of said mobile terminal from said reference  
position.

11. The mobile terminal of claim 10 wherein said position estimator is in a removable  
device removably attached to said mobile terminal.

25

5 12. The mobile terminal of claim 10 wherein said position estimator comprises a GPS receiver.

13. A method of initiating a search for a control channel in a communications network by a mobile terminal, said method comprising:

10 storing at least one reference position indicative of the location of said communications network in said mobile terminal;

determining the current position of said mobile terminal;

computing the distance of said current position of said mobile terminal from said reference position; and

15 initiating a search for a channel based on said distance between said mobile terminal and said communication network.

14 The method of claim 13, including establishing communication between said and said mobile terminal and said communication network.

20 15. The method of claim of claim 14 wherein establishing communications between said mobile terminal and said communications network comprises establishing communication with a private radiocommunication system.

- 5 16. The method of claim 15 wherein establishing communication with a private  
radiocommunication system comprises establishing communication with said private  
radiocommunication system via a short-range air interface.
17. The method of claim 16 wherein establishing communication with said private  
10 radiocommunication system via a short-range air interface comprises establishing  
communication with said private radiocommunication system via a Bluetooth interface.
18. The method of claim 13, wherein determining the current position of said mobile  
terminal comprises receiving signals from navigation satellites and calculating said  
15 current position from said signals received from said navigation satellites.
19. The method of claim 13, wherein determining said current position of said mobile  
terminal is repeated at intervals dependant on said distance of said current position of said  
mobile terminal from said reference position.
- 20 20. The method of claim 13, further comprising determining the rate of change in said  
position of said mobile terminal relative to said reference position.
21. The method of claim 20, wherein determining said current position of said mobile  
25 terminal is repeated at intervals dependant on said rate of change of distance of said  
mobile terminal from said reference position.

5

22. The method of claim 20, including determining the rate of change in said position of said mobile terminal relative to said reference position and initiating a search for a channel when: (i) said distance between the mobile terminal and the reference position is less than said predetermined distance, and, (ii) said rate of change in said position of said mobile terminal relative to said reference position exceeds a predetermined value.

23. A mobile terminal comprising:  
a transceiver transmitting and receiving signals over a wireless channel;  
memory storing at least one reference position indicative of the location of a  
communications network;  
a position estimator to determine a current position of said mobile terminal; and  
control logic including a processor to calculate the distance of said mobile terminal from said reference position based on said current position of said mobile terminal and to initiate a search for a channel based on said calculated distance.

24. The mobile terminal of claim 23, wherein said position estimator comprises a receiver adapted to receive signals from navigation satellites and to calculate said current position from said received signals.

25

5 25. The mobile terminal of claim 23, wherein said control logic further calculates the rate of change of said current position relative to said reference position.

26. The mobile terminal of claim 25, wherein said control logic updates said current position at a frequency dependant on said rate of change of said current position relative  
10 to said reference position.

27. The mobile terminal of claim 23, wherein said control logic further calculates the rate of change of said current position of said mobile terminal relative to said reference position, and initiates a search for a channel based on said calculated distance between  
15 said mobile terminal and said reference position and said rate of change of said current position of said mobile terminal relative to said reference position.

28. The mobile terminal of claim 23 wherein said mobile terminal further comprises a Bluetooth interface.  
20

29. A method for controlling the initiation of searches by a mobile terminal for a channel associated with a private radiocommunication system, said method comprising:  
storing a reference position within the mobile terminal, said reference position  
being within the boundaries of the private radiocommunication system;  
25 determining the current position of said mobile terminal;

5           computing the distance of said current position of said mobile terminal from said  
            reference position; and  
  
            initiating a search for a channel provided by said private radiocommunication  
            system based on said computed distance between said current position of  
            said mobile terminal and said reference position.

10

30.     The method of claim 29, wherein determining the current position of said mobile  
terminal and computing the distance of said current position of said mobile terminal from  
said reference position are preformed repeatedly.

15

31.     The method of claim 29, wherein said mobile terminal repeatedly searches for a  
channel provided by said private radiocommunication system as long as said distance of  
said current position of said mobile terminal from said reference position is less than said  
predetermined distance.

20

32.     The method of claim 29, further including determining the rate of change of said  
distance between said current position of said mobile terminal and said reference position  
and initiating a search for a channel provided by said private radiocommunication system  
in response to: (i) said rate of change being greater than a predetermined value, and, (ii)  
said distance between said current position of said mobile terminal and said reference

25     position being less than a predetermined distance

5 33. The method of claim 29, wherein initiating a search for a channel provided by said private radiocommunication system is further based on the rate of change of said distance between said current position of said mobile terminal and said reference position.

34. A method of controlling the initiation of a search by a mobile terminal for a  
10 channel associated with a radiocommunication system comprising:  
repeatedly determining the location of the mobile terminal with respect to a  
reference position associated with the radio communication system; and  
initiating a search for a channel associated with said radio communication system  
if the computed distance between the mobile terminal and the reference  
15 position is less than a predetermined distance.

35. The method of claim 34 further comprising:  
repeatedly determining the rate of change of said distance between said mobile  
terminal and said reference position; and  
20 initiating a search for the channel associated with said radio communication system when:  
(i) the distance between said mobile terminal and said reference position is  
less than said predetermined distance, and,  
(ii) (ii) when the rate of change of the distance between said mobile terminal  
25 and said reference position exceeds a predetermined value.

## ABSTRACT OF THE DISCLOSURE

[illegible]

## Declaration and Power of Attorney for Patent Application

As below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name,

I believe that I am the original, first and sole inventor of the subject matter which is claimed and for which a patent is sought on the invention entitled **METHOD TO CONTROL THE UPDATE FREQUENCY OF A POSITIONING DEVICE IN A MOBILE TERMINAL**, the specification of which

☒ is attached hereto.

(Check one)

☐ was filed on \_\_\_\_\_ as  
Application Serial Number \_\_\_\_\_  
and was amended on \_\_\_\_\_  
(if applicable)

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me which is material to patentability (as defined in C.F.R. §1.56) in connection with the examination of this application.

I hereby claim foreign benefits under Title 35, United States Code, §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

### Declaration and Power of Attorney for Patent Application

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, §1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

**Power of Attorney:** As a named inventor, I hereby appoint the following agents/attorneys to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

Kermit D. Lopez  
Registration Number 41,953

David R. Irvin  
Registration Number 42,682

David K. Purks  
Registration Number 40,133

I. Nelson Wakefield  
Registration Number 45,190

Debra K. Stephens  
Registration Number 38,211

Thomas M. Croft  
Registration Number 44,051

Kevin A. Sembrat  
Registration Number 36,673

Gary R. Kuhn  
Registration Number 44,198

Mark C. Terrano  
Registration Number 40,200

Jon Han  
Registration Number 41,403

Stephen A. Calogero  
Registration Number 41,491

Dennis J. Williamson  
Registration Number 32,338

Attorney Docket Number  
P-4015.677/P12448(US1)-RCUR

## Declaration and Power of Attorney for Patent Application

And I also hereby appoint the Attorneys and Patent Agents of **Coats & Bennett, P.L.L.C.**, as identified by **Customer Number 24112** in the records of the United States Patent and Trademark Office and as updated from time to time, to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith.
